' C. antarctica lipase and lipase variants.

FIELD OF THE INVENTION

The present invention relates to novel lipase enzyme variants with improved properties, DNA constructs coding for the expression of said variants, host cells capable of expressing the variants from the DNA constructs, as well as a method of producing the variants by cultivation of said host cells. Furthermore, the present invention relates to a recombinant essentially pure Candida antarctica lipase and variants thereof 10 as well as a DNA sequence encoding the said lipase or variants thereof.

BACKGROUND OF THE INVENTION

A wide variety of lipases of microbial and mammalian origin are known. The amino acid sequence of many of these lipases have 15 been elucidated and analyzed with respect to structural and functional elements important for their catalytic function, see, for instance, Winkler et al., 1990 and Schrag et al., 1991. It has been found that the lipase enzyme upon binding of a lipid substrate and activation undergoes a conformational 20 change, which inter alia, results in an exposure of the active site to the substrate. This conformational change together with the presumed interaction between enzyme and substrate have been discussed by, inter alia, Brady et al., 1990, Brzozowski et al., 1991, Derewenda et al., 1992.

25 Based on the knowledge of the structure of a number of lipases, it has been possible to construct lipase variants having improved properties by use of recombinant DNA techniques. Thus, WO 92/05249 discloses the construction of certain lipase variants, in which the lipid contact zone has been modified so as 30 to provide the variants with different substrate specificities and/or an improved accessibility of the active site of the

, lipase to a lipid substrate. The modifications involve changing the electrostatic charge, hydrophobicity or the surface conformation of the lipid contact zone by way of amino acid substitutions.

5 Although the structural and functional relationship of lipases have been the subject of a number of studies as described in the above cited references, the research has mainly focused on the macroscopic characteristics of the lipases upon substrate binding and activation, whereas the identity of the amino acids 10 actually involved in the substrate binding and catalytic activity has been discussed only to a lesser extent.

#### SUMMARY OF THE INVENTION

By sequence alignment analysis combined with analysis of the structure and activity of a number of lipases, the present 15 inventors have now surprisingly found that the presence of certain amino acids, especially tryptophan, in a critical position of the lipase seems to be important for optimal catalytic activity.

It is consequently an object of the present invention to modify 20 lipases which do not comprise such an amino acid residue in the critical position (which lipases in the present context are termed parent lipases) by replacing the amino acid residue located in this position with an amino acid residue which gives rise to a variant having an increased specific activity.

25 More specifically, in one aspect the present invention relates to a lipase variant of a parent lipase comprising a trypsin-like catalytic triad including an active serine located in a predominantly hydrophobic, elongated binding pocket of the lipase molecule and, located in a critical position of a lipid 30 contact zone of the lipase structure, an amino acid residue different from an aromatic amino acid residue, which interacts

with a lipid substrate at or during hydrolysis, in which lipase variant said amino acid residue has been replaced by an aromatic amino acid residue so as to confer to the variant an increased specific activity as compared to that of the parent s lipase.

In the present context, the term "trypsin-like" is intended to indicate that the parent lipase comprises a catalytic triad at the active site corresponding to that of trypsin, i.e. the amino acids Ser, His and one of Asp, Glu, Asn or Gln.

10 Lipases degrades triglycerides down to fatty acids, glycerol and di- and/or monoglycerides. The lipase action is depending on interfacial activation of the lipase in the presence of substrate surfaces. On activation lipases change their conformation in such a manner that their surface hydrophobicity in an 15 area around the active site is increased. The interfacial activation of lipases is e.g. discussed by Tilbeurgh et al. (1993).

All lipases studied until now have been found to comprise at least one surface loop structure (also termed a lid or a flap) 20 which covers the active serine when the lipase is in inactive form (an example of such a lipase is described by Brady et al., 1990). When the lipase is activated, the loop structure is shifted to expose the active site residues, creating a surface surrounding the active site Ser, which has an increased surface 25 hydrophobicity and which interacts with the lipid substrate at or during hydrolysis. For the present purpose, this surface is termed the "lipid contact zone", intended to include amino acid residues located within or forming part of this surface, optionally in the form of loop structures. These residues may 30 participate in lipase interaction with the substrate at or during hydrolysis where the lipase hydrolyses triglycerides from the lipid phase when activated by contact with the lipid surface.

The lipid contact zone contains a binding area (a so-called binding pocket) for the lipid substrate which is the part of the lipid contact zone to which the lipid substrate binds before hydrolysis. This binding area again contains a so-called hydrolysis pocket, which is situated around the active site Ser, and in which the hydrolysis of the lipid substrate is believed to take place. In all known lipases to day the lipid contact zone is easily recognized, e.g. from a three-dimensional structure of the lipase created by suitable computer programs. The conformation of an inactive and activated lipase, respectively, is shown in Fig. 1 which is further discussed below.

In the present context, the "critical position" of the lipase molecule is the position in the lipid contact zone of the lipase molecule, which is occupied by an amino acid residue which interacts with the lipid substrate and which is different from an aromatic amino acid residue.

In another aspect the present invention relates an C. antarctica lipase A which is essentially free from other C. antarctica substances and which comprises the amino acid sequence identified in SEQ ID No. 2 or a variant thereof which

- 1) has lipase activity,
  - 2) reacts with an antibody reactive with at least one epitope of the C. antarctica lipase having the amino acid sequence shown in SEQ ID No. 2, and/or
  - 3) is encoded by a nucleotide sequence which hybridizes with an oligonucleotide probe prepared on the basis of the full or partial nucleotide sequence shown in SEQ ID No. 1 encoding the C. antarctica lipase A.
- 30 The C. antarctica lipase A of the invention has a number of desirable properties including a high thermostability and

activity at acidic pH and may advantageously be produced by use of recombinant DNA techniques, e.g. using the procedures described below. Thus, the lipase A of the invention may be obtained in a higher purity and a higher amount than the C. antarctica lipase A purified from wild type C. antarctica which is described in WO 88/02775.

Furthermore, the present invention relates to a DNA sequence encoding the C. antarctica lipase A having the amino acid sequence identified in SEQ ID No. 2 or a modification of said 10 DNA sequence encoding a variant of the C. antarctica lipase A as defined above.

In the present context "C. antarctica lipase A" is used interchangeably with "lipase A" and the variant of the C. antarctica lipase A is termed "lipase A variant".

15 The present invention also relates to a DNA construct comprising a DNA sequence encoding a lipase variant as indicated above or a DNA sequence encoding the C. antarctica lipase A, a recombinant expression vector carrying said DNA construct, a cell transformed with the DNA construct or the expression 20 vector, as well as a method of producing a lipase variant of the invention by culturing said cell under conditions conducive to the production of the lipase variant, after which the lipase variant is recovered from the culture.

It will be understood that lipase variants of the present 25 invention having an increased specific activity as compared to their parent lipases may be used for the same purposes as their parent lipases, advantageously in a lower amount due to their higher specific activity.

Accordingly, the present invention relates to the use of a 30 lipase variant of the invention as a detergent enzyme; as a digestive enzyme; in ester hydrolysis, ester synthesis or interesterification; or the use of the lipase variant to avoid pitch

trouble arising, e.g., in processes for preparing mechanical pulp and in paper-making processes using mechanical pulp.

#### DETAILED DISCLOSURE OF THE INVENTION

As indicated above, the present inventors have found that the presence of certain aromatic amino acids, especially tryptophan, located in the lipid contact zone of the lipase molecule is important for optimal catalytic activity.

The importance of the presence of an aromatic amino acid residue and in particular a tryptophan residue was found in connection with a study of mutants of a Humicola lanuginosa lipase which comprises a tryptophan residue at the critical position in the lipid contact zone, i.e. the amino acid number 89 in the amino acid sequence of the H. lanuginosa lipase published in EP 0 305 216. In the H. lanuginosa mutants this tryptophan residue was replaced by phenylalanine, tyrosine, histidine, isoleucine, glutamic acid and glycine, respectively. It was found that the specific activity of these mutants decreased (in the order indicated above) from 100% of the wild type lipase to about 10% of the phenylalanine mutant and down to about 2% for the glycine mutant.

Without being limited to any theory it is presently believed that the amino acid residue present in the critical position, e.g. on top of or in the proximity of the active serine, may be involved in a) stabilization of the tetrahedral intermediate formed from the lipase and the substrate during the activation of the lipase, and b) in the activation of the replacement of the lid region covering the active serine in the inactive enzyme. When tryptophan is present in this position, it is contemplated that optimal performance with respect to a) as well as b) above is obtained. Thus, it is believed that tryptophan gives rise to the formation of the most stable tetrahedral intermediate (which means a lowering of the activation energy

, needed for the catalysis to take place), and further improves the performance of the enzyme with respect to the activation of the lid opening which is essential for any catalysis to take place.

5 In connection with a) above it has been observed that the best acting lipase variants contain an unsaturated ring system in the side-chain. The far the biggest unsaturated system is tryptophan, then tyrosine, phenylalanine and histidine. These sidechains have a pi-electron system ("the unsaturation") that 10 could be important for the proton transfer in the catalysis resulting in a lower activation energy for creating the tetrahedral intermediate where proton transfer has taken place from active site histidine to serine to the oxyanion hole created after lid activation and opening.

15 From the above theoretical explanation it will be understood that the optimal amino acid to be present in the critical position, e.g. on top of or in the proximity of the active serine, is tryptophan. However, when the parent lipase is one which does not contain any aromatic amino acid residue or any 20 amino acid residue with an unsaturated ring system in the side-chain in this position, such amino acids may advantageously be substituted into this position.

Thus, when the parent lipase, in the critical position, has an amino acid residue which does not comprise an unsaturated ring 25 system in the side-chain, an amino acid residue having such an unsaturated ring-system, e.g. an aromatic amino acid (tryptophan, tyrosine, phenylalanine or histidine) may be substituted into the critical position. When the amino acid residue in the critical position of the parent lipase is 30 histidine, it may advantageously be replaced by phenylalanine, tyrosine and most preferably tryptophan, when the amino acid residue is tyrosine, it may advantageously be replaced by phenylalanine and most preferably tryptophan, and when the

amino acid residue is phenylalanine it may advantageously be replaced by tryptophan.

While the critical position in some lipases is contemplated to be any position within the lipid contact zone, the critical 5 position will normally be located in the binding pocket of the lipase molecule, and preferably in the hydrolysis pocket thereof. For most lipases it is believed that the critical amino acid residue is positioned on top of or in the proximity of the active site.

10 The amino acid residue occupying this position may be identified in any lipase by 1) sequence alignment studies in which the amino acid sequence of the lipase in question is aligned with the amino acid sequence of other lipases, in which the amino acid residue positioned on top of or in the proximity of 15 the active serine has been identified, so as to identify the presumed position of said amino acid residue, and/or 2) an analysis of the three-dimensional structure of the lipase in question using standard display programmes such as INSIGHT (Biosym Technologies Inc., San Diego, USA), so as identify the 20 amino acid sequence on top of or in the proximity of the active serine.

More specifically, on the basis of a computer program such as INSIGHT displaying lipase coordinates in accordance with well-known technology, it is simple to point out which part of the 25 lipase which contains the lipid contact zone. 1/ if the structure of the lipase is in a non-activated form, the lipid contact zone is identified by the direction of sidechains of the active site Ser. 2/ if the structure is in the activated form one may additionally base the identification on a colour-30 ing of all hydrophobic residues in a colour different from the other residues. By this procedure in which a cpk model of the structure is created, the hydrophobic surface specific for the lipid contact zone may be identified. The active site Ser is located within this more hydrophobic part of the molecule.

In some lipases the critical amino acid residue is located in the surface loop structure covering the active site, or in one or more of the surface loop structures found to form part of the surface of the lipid contact zone, such as of the binding pocket or hydrolysis pocket.

Although the critical position is normally considered to be constituted of only one amino acid residue it may be advantageous to replace two or more residues, preferably with a tryptophan residue as explained above, in order to obtain a further increased specific acitivity.

It is contemplated that it is possible to increase the specific activity of parent lipases which do not have a tryptophan residue in the critical position at least 2 times, such as at least 3 and preferably at least 4 or even 5, 6 or 7 times by modifications as disclosed herein.

It is contemplated that lipase variants as defined herein having an increased substrate specificity may be prepared on the basis of parent lipases of various origins. Thus, the parent lipase may be a microbial lipase or a mammalian lipase.

When the parent lipase is a microbial lipase, it may be selected from yeast, e.g. Candida, lipases, bacterial, e.g. Pseudomonas, lipases or fungal, e.g. Humicola or Rhizomucor lipases.

One preferred lipase variant is one, in which the parent lipase is derived from a strain of Candida antarctica, in particular one in which the parent lipase is lipase A of C. antarctica, preferably the one which has the amino acid sequence shown in SEQ ID No. 2 or a lipase A variant thereof as defined herein. The lipase variant of this C. antarctica lipase A preferably has the amino acid sequence shown in SEQ ID No. 2 in which the phenylalanine 139 of the parent lipase has been replaced by a tryptophan residue. The construction of this variant and the

analysis of the properties thereof is discussed in Example 3, 5 and 6.

A lipase variant of the invention may, as mentioned above, be prepared on the basis of a parent lipase derived from a strain 5 of a Pseudomonas species, e.g. Ps. fragi. An example of a suitable Ps. fragi lipase which has an amino acid residue different from tryptophan positioned on top of or in the proximity of the active serine, is the one described by Aoyama et al., 1988. A lipase variant according to the present 10 invention may be constructed by replacing the phenylalanine residue 29 in the amino acid sequence of said lipase shown in SEQ ID No. 3 by a tryptophan residue.

An example of a fungal lipase suitable as a parent lipase for the construction of a lipase variant of the invention is one 15 derived from Rhizopus, especially from R. delemar or R. niveus, the amino acid sequence of which latter is disclosed in, e.g., JP 64-80290. In order to construct a lipase variant according to the present invention from this parent lipase, the alanine residue at position 117 is to be replaced with an aromatic 20 amino acid residue such as tryptophan. The sequence alignment of the R. niveus lipase sequence (SEQ ID No. 5) and an Rhizomucor miehei lipase sequence (containing a tryptophan residue) (SEQ ID No. 4) is illustrated below. From this alignment the critical position of the R. niveus lipase may be determined.

The present inventors have surprisingly found that non-pancreatic lipases such as gastric, lingual, or hepatic lipases 15 have the common feature that the amino acid residue which has been identified to be the one located in the critical position of the lipase molecule, normally on top of or in the proximity of the active serine, is different from tryptophan. This is in contrast to pancreatic lipases which generally have been found 20 to have a tryptophan residue in this position. Thus, in the present context, non-pancreatic mammalian lipases may advantageously be used as "parent lipases" for the construction of lipase variants of the invention.

Accordingly, lipase variants as disclosed herein which is of 25 mammalian origin is advantageously prepared from a parent lipase of non-pancreatic, such as gastric, lingual or hepatic origin. Such mammalian lipases may be derived from humans, rats, mice, pigs, dogs or other mammals. Specific examples of such mammalian lipases includes a rat lingual lipase having the 30 sequence identified as A23045 (Docherty et al., 1985), a rat hepatic lipase having the sequence identified as A27442

, (Komaromy and Schotz, 1987), a human hepatic lipase having the sequence identified as A33553 (Datta et al., 1988), a human gastric lipase having the sequence identified as S07145 (Bodmer et al., 1987), and a Bio Salt Activated Lipase (BSAL) having the sequence identified as A37916 (Baba et al., 1991) all of which were analysed with respect to the critical position in the sequence alignment analysis illustrated below. The pancreatic lipases included in this sequence alignment study were a murine pancreatic lipase, A34671 (Grusby et al., 1990), a porcine pancreatic lipase, A00732 (Caro et al., 1981), a human pancreatic lipase, A34494 (Lowe et al., 1989), and a canine pancreatic lipase having the sequence B24392 (Mickel et al., 1989). The amino acid sequences of each of the lipases mentioned have the accession numbers listed above and are available from publically available databases.

As mentioned above the present invention also relates to a C. antarctica lipase A essentially free from other C. antarctica substances, which has the amino acid sequence shown in SEQ ID No. 2 or a variant therof which

5 1) has lipase activity,

2) reacts with an antibody reactive with at least one epitope of C. antarctica lipase A having the amino acid sequence shown in SEQ ID No. 2, and/or

3) is encoded by a nucleotide sequence which hybridizes with an 10 oligonucleotide probe prepared on the basis of the full or partial nucleotide sequence shown in SEQ ID No. 1 encoding the C. antarctica lipase A.

In the present context, the term "variant" is intended to indicate a lipase A variant which is derived from the C. antarctica lipase A having the amino acid sequence shown in SEQ 15 ID No. 2, or a naturally occurring variant. Typically, the variant differ from the native lipase A by one or more amino acid residues, which may have been added or deleted from either or both of the N-terminal or C-terminal end of the lipase, 20 inserted or deleted at one or more sites within the amino acid sequence of the lipase or substituted with one or more amino acid residues within, or at either or both ends of the amino acid sequence of the lipase.

Furthermore, the variant of the invention has one or more of 25 the characterizing properties 1)-3) mentioned above. Property 1), i.e. the "lipase activity" of the variant may be determined using any known lipase assay, e.g. the Standard LU assay described in the Methods section below.

Property 2), i.e. the reactivity of the variant of the invention with an antibody raised against or reactive with at least 30 one epitope of the C. antarctica lipase A having the amino acid

, sequence shown in SEQ ID No. 2 below may be determined by polyclonal antibodies produced in a known manner, for instance by immunization of a rabbit with the C. antarctica lipase A of the invention. The antibody reactivity may be determined using 5 assays known in the art, examples of which are Western Blotting or radial immunodiffusion assay.

Property 3) above, involving hybridization, may be performed using an oligonucleotide probe prepared on the basis of the full or partial cDNA sequence encoding the C. antarctica lipase 10 A, the amino acid sequence of which is identified in SEQ ID No. 2, as a hybridization probe in a hybridization experiment carried out under standard hybridization conditions. For instance, such conditions are hybridization under specified conditions, e.g. involving presoaking in 5xSSC and prehybridizing for 1h at ~40°C in a solution of 20% formamide, 15 5xDenhardt's solution, 50mM sodium phosphate, pH 6.8, and 50µg of denatured sonicated calf thymus DNA, followed by hybridization in the same solution supplemented with 100µM ATP for 18h at ~40°C, or other methods described by e.g. Sambrook et al., 20 1989.

The nucleotide sequence on the basis of which the oligonucleotide probe is prepared is conveniently the DNA sequence shown in SEQ ID No. 1.

As stated above in a further aspect the present invention 25 relates to a DNA sequence encoding C. antarctica lipase A having the amino acid sequence shown in SEQ ID No. 2 or a modification of said DNA sequence which encodes a variant of C. antarctica lipase A which

1) has lipase activity,

30 2) reacts with an antibody reactive with at least one epitope of the C. antarctica lipase A having the amino acid sequence shown in SEQ ID No. 2, and/or

, 3) is encoded by a nucleotide sequence which hybridizes with an oligonucleotide probe prepared on the basis of the full or partial nucleotide sequence shown in SEQ ID No. 1 encoding the C. antarctica lipase A.

5 Examples of suitable modifications of the DNA sequence are nucleotide substitutions which do not give rise to another amino acid sequence of the encoded enzyme, but which may correspond to the codon usage of the host organism into which the DNA sequence is introduced or nucleotide substitutions 10 which do give rise to a different amino acid sequence, without, however, impairing the above stated properties of the enzyme. Other examples of possible modifications are insertion of one or more nucleotides into the sequence, addition of one or more nucleotides at either end of the sequence and deletion of one 15 or more nucleotides at either end of or within the sequence.

Methods of preparing lipase variants of the invention

Several methods for introducing mutations into genes are known in the art. After a brief discussion of cloning lipase-encoding DNA sequences, methods for generating mutations at specific 20 sites within the lipase-encoding sequence will be discussed.

Cloning a DNA sequence encoding a lipase

The DNA sequence encoding a parent lipase or the C. antarctica lipase A as defined herein may be isolated from any cell or microorganism producing the lipase in question by various 25 methods, well known in the art. First a genomic DNA and/or cDNA library should be constructed using chromosomal DNA or messenger RNA from the organism that produces the lipase to be studied. Then, if the amino acid sequence of the lipase is known, homologous, labelled oligonucleotide probes may be 30 synthesized and used to identify lipase-encoding clones from a genomic library of bacterial DNA, or from a fungal cDNA library. Alternatively, a labelled oligonucleotide probe containing sequences homologous to lipase from another strain of bacteria or fungus could be used as a probe to identify

lipase-encoding clones, using hybridization and washing conditions of lower stringency.

Yet another method for identifying lipase-producing clones would involve inserting fragments of genomic DNA into an expression vector, such as a plasmid, transforming lipase-negative bacteria with the resulting genomic DNA library, and then plating the transformed bacteria onto agar containing a substrate for lipase. Those bacteria containing lipase-bearing plasmid will produce colonies surrounded by a halo of clear agar, due to digestion of the substrate by secreted lipase.

Alternatively, the DNA sequence encoding the enzyme may be prepared synthetically by established standard methods, e.g. the phosphoamidite method described by S.L. Beaucage and M.H. Caruthers (1981) or the method described by Matthes et al. 15 (1984). According to the phosphoamidite method, oligonucleotides are synthesized, e.g. in an automatic DNA synthesizer, purified, annealed, ligated and cloned in appropriate vectors.

Finally, the DNA sequence may be of mixed genomic and synthetic, mixed synthetic and cDNA or mixed genomic and cDNA origin 20 prepared by ligating fragments of synthetic, genomic or cDNA origin (as appropriate), the fragments corresponding to various parts of the entire DNA sequence, in accordance with standard techniques. The DNA sequence may also be prepared by polymerase chain reaction (PCR) using specific primers, for instance as 25 described in US 4,683,202 or R.K. Saiki et al. (1988).

Site-directed mutagenesis of the lipase-encoding sequence

Once a lipase-encoding DNA sequence has been isolated, and desirable sites for mutation identified, mutations may be introduced using synthetic oligonucleotides. These oligonucleotides 30 contain nucleotide sequences flanking the desired mutation sites; mutant nucleotides are inserted during oligonucleotide synthesis. In a specific method, a single-stranded gap of DNA, bridging the lipase-encoding sequence, is created in a vector

carrying the lipase gene. Then the synthetic nucleotide, bearing the desired mutation, is annealed to a homologous portion of the single-stranded DNA. The remaining gap is then filled in with DNA polymerase I (Klenow fragment) and the construct is ligated using T4 ligase. A specific example of this method is described in Morinaga et al. (1984). U.S. Patent number 4,760,025 discloses the introduction of oligonucleotides encoding multiple mutations by performing minor alterations of the cassette, however, an even greater variety of mutations can be introduced at any one time by the Morinaga method, because a multitude of oligonucleotides, of various lengths, can be introduced.

Another method of introducing mutations into lipase-encoding sequences is described in Nelson and Long (1989). It involves 15 the 3-step generation of a PCR fragment containing the desired mutation introduced by using a chemically synthesized DNA strand as one of the primers in the PCR reactions. From the PCR-generated fragment, a DNA fragment carrying the mutation may be isolated by cleavage with restriction endonucleases and 20 reinserted into an expression plasmid.

#### Expression of lipase variants

According to the invention, a *C. antarctica* lipase A-coding sequence or a mutated lipase-coding sequence produced by methods described above or any alternative methods known in the 25 art, can be expressed, in enzyme form, using an expression vector which typically includes control sequences encoding a promoter, operator, ribosome binding site, translation initiation signal, and, optionally, a repressor gene or various activator genes. To permit the secretion of the expressed 30 protein, nucleotides encoding a "signal sequence" may be inserted prior to the lipase-coding sequence. For expression under the direction of control sequences, a target gene to be treated according to the invention is operably linked to the control sequences in the proper reading frame. Promoter 35 sequences that can be incorporated into plasmid vectors, and

, which can support the transcription of the mutant lipase gene, include but are not limited to the prokaryotic  $\beta$ -lactamase promoter (Villa-Kamaroff et al. (1978) and the tac promoter (DeBoer, et al., 1983). Further references can also be found 5 in "Useful proteins from recombinant bacteria" (1980).

According to one embodiment a strain of Bacillus, e.g. B. subtilis, B. licheniformis or B. lentus, or a strain of E. coli is transformed by an expression vector carrying the lipase A or the mutated DNA. If expression is to take place in a secreting 10 microorganism such as B. subtilis a signal sequence may follow the translation initiation signal and precede the DNA sequence of interest. The signal sequence acts to transport the expression product to the cell wall where it is cleaved from the product upon secretion. The term "control sequences" as 15 defined above is intended to include a signal sequence, when is present.

The lipase or lipase variants of the invention may further be produced by using a yeast cell has a host cell. Examples of suitable yeast host cells include a strain of Saccharomyces, 20 such as S. cerevisiae, or a strain of Hansenula, e.g. H. polymorpha or Pichia, e.g. P. pastoris.

In a currently preferred method of producing lipase A or lipase variants of the invention, a filamentous fungus is used as the host organism. The filamentous fungus host organism may 25 conveniently be one which has previously been used as a host for producing recombinant proteins, e.g. a strain of Aspergillus sp., such as A. niger, A. nidulans or A. oryzae. The use of A. oryzae in the production of recombinant proteins is extensively described in, e.g. EP 238 023.

30 For expression of lipase variants in Aspergillus, the DNA sequence coding for the lipase A or the lipase variant is preceded by a promoter. The promoter may be any DNA sequence exhibiting a strong transcriptional activity in Aspergillus and

, may be derived from a gene encoding an extracellular or intracellular protein such as an amylase, a glucoamylase, a protease, a lipase, a cellulase or a glycolytic enzyme.

Examples of suitable promoters are those derived from the gene 5 encoding A. oryzae TAKA amylase, Rhizomucor miehei aspartic proteinase, A. niger neutral  $\alpha$ -amylase, A. niger acid stable  $\alpha$ -amylase, A. niger glucoamylase, Rhizomucor miehei lipase, A. oryzae alkaline protease or A. oryzae triose phosphate isomerase.

10 In particular when the host organism is A. oryzae, a preferred promoter for use in the process of the present invention is the A. oryzae TAKA amylase promoter as it exhibits a strong transcriptional activity in A. oryzae. The sequence of the TAKA amylase promoter appears from EP 238 023.

15 Termination and polyadenylation sequences may suitably be derived from the same sources as the promoter.

The techniques used to transform a fungal host cell may suitably be as described in EP 238 023.

To ensure secretion of the lipase A or the lipase variant from 20 the host cell, the DNA sequence encoding the lipase variant may be preceded by a signal sequence which may be a naturally occurring signal sequence or a functional part thereof or a synthetic sequence providing secretion of the protein from the cell. In particular, the signal sequence may be derived from a 25 gene encoding an Aspergillus sp. amylase or glucoamylase, a gene encoding a Rhizomucor miehei lipase or protease, or a gene encoding a Humicola cellulase, xylanase or lipase. The signal sequence is preferably derived from the gene encoding A. oryzae TAKA amylase, A. niger neutral  $\alpha$ -amylase, A. niger acid-stable 30  $\alpha$ -amylase or A. niger glucoamylase.

The medium used to culture the transformed host cells may be any conventional medium suitable for culturing Aspergillus cells. The transformants are usually stable and may be cultured in the absence of selection pressure. However, if the transformants are found to be unstable, a selection marker introduced into the cells may be used for selection.

The mature lipase protein secreted from the host cells may conveniently be recovered from the culture medium by well-known procedures including separating the cells from the medium by 10 centrifugation or filtration, and precipitating proteinaceous components of the medium by means of a salt such as ammonium sulphate, followed by chromatographic procedures such as ion exchange chromatography, affinity chromatography, or the like.

It will be understood that the lipase variants of the invention 15 are contemplated to be active towards the same type of substrates as their parent lipases, with an improved specific activity. Thus, the lipase variants of the invention are contemplated to be useful for the same purposes as their parent lipases.

20 Accordingly, lipase variants of the invention prepared from a parent lipase useful as a detergent enzyme may be used as an active ingredient in a detergent additive or a detergent composition.

Another contemplated use of lipase variants of the invention, 25 is as digestive enzymes, e.g. in the treatment of cystic fibrosis.

A third use of the lipase variants of the invention, especially variants of C. antarctica lipases are in lipase-catalysed processes such as in ester hydrolysis, ester synthesis and 30 interesterification. The use of lipases in these processes is discussed in detail in WO 88/02775 (Novo Nordisk A/S), the content of which is incorporated herein by reference. Further-

, more, as the C. antarctica is an unspecific lipase, it may be used for randomization, e.g. in the preparation of margarine. Also the lipase variants of the invention may be used to avoid pitch trouble that arises in the production process for mechanical pulp or in a paper-making process using mechanical pulp, e.g. as described in PCT/DK92/00025 (Novo Nordisk A/S), the content of which is incorporated herein by reference.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is described in the following with reference to the appended drawings, in which

Fig. 1 is a computer model showing the three-dimensional structure of the lipid contact zone of the H. lanuginosa lipase described in WO 92/05249 when the lipase is in inactive (closed) and active (open) form, respectively. "White" residues represent hydrophobic amino acids (Ala, Val, Leu, Ile, Pro, Phe, Trp, Gly and Met), "yellow" residues represent hydrophilic amino acids (Thr, Ser, Gln, Asn, Tyr and Cys), "blue" residues represent positively charged amino acids (Lys, Arg and His), and "red" residues represent negatively charged amino acids (Glu and Asp).

Figs. 2 and 3 illustrate the scheme for the construction of the expression plasmid pMT1229 (see Example 1).

The present invention is further illustrated in the following examples which are not intended, in any way, to limit the scope of the invention as claimed.

**MATERIALS****Plasmids and microorganisms**

E. coli MT172 (a K12 restriction deficient E. coli MC1000 derivative)

**10 GENERAL METHODS****Site-directed in vitro mutagenesis of lipase genes**

The three different approaches described in WO 92/05249 may be used for introducing mutations into the lipase genes, i.e. the oligonucleotide site-directed mutagenesis which is described by 15 Zoller & Smith, DNA, Vol. 3, No. 6, 479-488 (1984), the PCR method as described in Nelson & Long, Analytical Biochemistry, 180, 147-151 (1989), and the so-called "cassette mutagenesis" technique, in which a segment between two restriction sites of the lipase-encoding region is replaced by a synthetic DNA fragment carrying the desired mutation. Use of the latter technique 20 is illustrated in Example 2.

**Determination of lipase specific activity**

Lipase activity was assayed using glycerine tributyrat as a substrate and gum-arabic as an emulsifier. 1 LU (Lipase Unit) 25 is the amount of enzyme which liberates 1 µmol titratable butyric acid per minute at 30°C, pH 7.0. The lipase activity was assayed by pH-stat using Radiometer titrator VIT90, Radiometer, Copenhagen. Further details of the assay are given in Novo Analytical Method AF 95/5, available on request.

## EXAMPLES

## EXAMPLE 1

**Cloning of Candida antarctica lipase A**

Chromosomal DNA of the C. antarctica strain LF058 (= DSM 3855  
5 deposited with the Deutsche Sammlung von Mikroorganismen (DSM)  
on September 29, 1986 under the terms of the Budapest Treaty,  
and further described in WO 88/02775) was prepared by opening  
of frozen cells by grinding with quartz and subsequent extrac-  
tion of DNA essentially as described by Yelton et al., (1984).  
10 The purified DNA was cut partially with Sau3A and, after  
agarose gel electrophoresis, fragments in the range of 3-9 kb  
were isolated. The sized Sau3A fragments were ligated into a  
BamH1-cut, dephosphorylated plasmid pBR322 (New England  
Biolabs). The ligation mix was transformed into the E. coli  
15 MT172. Approximately 50,000 transformant E. coli colonies were  
obtained, 80% of which contained an insert of LF058 DNA.

Using standard colony hybridization techniques (Maniatis et  
al., 1982) the colonies were screened with the  $^{32}\text{P}$ -phosphory-  
lated oligonucleotide probe NOR 440 (SEQ ID No. 7). NOR 440 is  
20 a degenerated (64) 17 mer based on the N-terminal determined  
from mature C. antarctica lipase A (SEQ ID No. 2). 34 colonies  
appeared positive after wash at low stringency ( $41^\circ\text{C}$  and 6 x  
SSC). Plasmids were prepared from these colonies and Southern  
analyzed after restriction with BstN1. The probe for the  
25 Southern was either the NOR 440 probe (SEQ ID No. 7) used for  
the colony hybridization (see above) or a  $^{32}\text{P}$ -labelled probe NOR  
438 (SEQ ID No. 6). NOR 438 is an oligonucleotide (a guess mer)  
where, at 13 positions, a base has been chosen on the basis of  
codon use in yeasts and filamentous fungi.

T T T (SEQ ID NO. 6)

guess positions indicated

5 Only one plasmid, pMT1076, contained a band which hybridised both to NOR 440 at low stringency (see above) and to NOR 438 at a somewhat higher stringency (55°C and 1 x SSC).

PMT1076 was restriction mapped and the DNA sequence determined by the Maxam-Gilbert method. The sequence covering the open reading frame is shown in SEQ ID No. 1. The open reading frame is seen to encode a putative signal sequence of 21 amino acids (according to the von Heine rules (von Heijne, G. (1986)) and furthermore a propeptide of 10 amino acids preceding the N-terminal of the mature lipase. The last two amino acids of the propeptide are Arg Arg, i.e. a typical cleavage site for endoproteolytic processing by enzymes of the S. cereviciae KEX-2 type. The amino acid composition of the mature protein (starting at position 32) encoded by the DNA sequence is in agreement with the amino acid composition determined for C. antarctica lipase A, cf. the following table:

Table IAmino acid composition of *C. antartica* lipase A (CALIP)

	Deduced from DNA sequence	By amino acid analysis (MC)
5 Ala	50	47
Arg	9	9
Asp/Asn	35	36
Cys	4	4
Gln/Gln	35	36
10 Gly	28	31
His	6	6
Ile	26	24
Leu	29	30
Lys	17	17
15 Met	2	3
Phe	20	19
Pro	33	33
Ser	26	27
Thr	27	28
20 Trp	5	4
Tyr	18	16
Val	27	26

Through a number of standard plasmid manipulations (Maniatis et al., 1982) illustrated in Figs. 2 and 3, the open reading frame 25 of *C. antarctica* lipase A was placed in the correct orientation between the alpha-amylase promoter of *A. oryzae* and the glucoamylase transcription terminator of *A. niger*. The resulting expression plasmid pMT1229 was transformed into *A. oryzae* A1560 as described in EP 305,216. Transformants were isolated 30 and grown as described in the above cited patents and the culture supernatants were analyzed for the presence of *C. antarctica* lipase A.

## EXAMPLE 2

**Construction of a plasmid expressing the F135W variant of  
Candida antarctica lipase A**

A 246 bp BamHI/BssHII fragment was synthesized in vitro on the basis of the nucleotide sequence of pMT1229 using oligonucleotide primers 3116 and 3117 in a PCR reaction. The primer 3117 includes a BssHII restriction site and a mutation in the 135 phe codon (TTC) to trp codon (TGG) which is marked with stars.

Oligonucleotide primer 3116 (F135W:256-276) (SEQ ID No. 8)  
10 5'-CAG AAC GAG GCG GTG GCC GAC-3'

Oligonucleotide primer 3117 (F135W:566-487) (SEQ ID No. 9)  
5'-TTC TTG AGC GCG CGG ATG CCG TCG AGG ATA GCC ATG CCC TCT TCG  
TAG CCA GCG ATG AAG GCG GCT TTC\* C\*AG CCT TCG TG-3'

The PCR reaction was performed by mixing the following components and incubating the mixture in a HYBAID™ thermal reactor.

Template pMT1229	10 ng/ $\mu$ l	1 $\mu$ l
H <sub>2</sub> O	46.5 $\mu$ l	
10 x PCR buffer	10 $\mu$ l	
20 2 mM dATP	10 $\mu$ l	
2 mM dTTP	10 $\mu$ l	
2 mM dCTP	10 $\mu$ l	
2 mM dGTP	10 $\mu$ l	
primer 3116	50.5 pmol/ $\mu$ l	1 $\mu$ l
25 primer 3117	70.5 pmol/ $\mu$ l	1 $\mu$ l
Tag polymerase		0.5 $\mu$ l

Step II 94°C	30 sec.	
30 50°C	30 sec.	30 cycle
72°C	2 min.	
Step III 72°C	5 min.	1 cycle

The resulting 310 bp fragment was isolated from a 2% agarose gel after electrophoresis and digested with BamHI and BssHII restriction enzymes. The resulting 264 bp BamHI/BssHII frag-

ment was likewise isolated from 2% agarose gel. This fragment was then ligated with

	pMT1229	BamHI/XbaI	0.3 kb
	pMT1229	BssHII/SphI	0.5 kb
5	pMT1229	SphI/XbaI	5.0 kb

The ligated DNA was transformed into *E. coli* strain MT172. Transformants which contained correct inserts were selected and their DNA sequence was determined by use of Sequenase (United States Biochemical Corporation). One resulting plasmid (pME-10 1178) contained a mutation in the amino acid position 135 (phe was mutated to trp).

pME1178 was cotransformed with pTOC90 which included the amdS gene from *A. nidulans* as a selective marker into the *A. oryzae* A1560 strain using the procedure described in WO 91/17243. *A. oryzae* transformants were reisolated twice on selective plates and stable transformants were characterized by rocket immunoelectrophoresis, using anti-*Candida* lipase A antibody. *Candida* lipase A produced by a transformant (strain MEA65) was further analyzed for specific activity.

#### 20 EXAMPLE 3

##### **Construction of a plasmid expressing the F139W variant of Candida antarctica lipase A**

A 246 bp BamHI/BssHII fragment was synthesized in vitro on the basis of the nucleotide sequence of the plasmid pMT1229 using 25 oligonucleotide primers 3116 and 3826 in a PCR reaction. The primer 3826 includes a BssHII restriction site and a mutation in the 139 phe codon (TTC) to trp codon (TGG) which is marked with stars.

Oligonucleotide primer 3116 is shown in Example 2.

Oligonucleotide primer 3826 (F139W:566-487) (SEQ ID No. 10)  
5'-TTC TTG AGC GCG CGG ATG CCG TCG AGG ATA GCC ATG CCC TCT TCG  
TAG CCA GCG ATC\* C\*AG GCG GCT TTG AAG CCT TCG TG-3'

5 A PCR reaction was performed by the method described in Example  
2. The 310 bp fragment was isolated from 2% agarose gel after  
electrophoresis and digested by BamHI and BssHII restriction  
enzymes. The resulting 264 bp BamHI/BssHII fragment was  
likewise isolated from 2% agarose gel. This fragment was then  
10 ligated with

pMT1229	BamHI/XbaI	0.3 kb
pMT1229	BssHII/SphI	0.5 kb
pMT1229	SphI/XbaI	5.0 kb

The ligated DNA was transformed into E. coli strain MT172.  
15 Transformants which contained correct inserts were selected and  
their DNA sequence was determined by use of Sequenase (United  
States Biochemical Corporation). One resulting plasmid (pME-  
1229) contained a mutation in the amino acid position 139 (phe  
was mutated to trp).

20 pME1229 was cotransformed with pTOC90 which included the amdS  
gene from *A. nidulans* as a selective marker into *A. oryzae* A  
1560 strain. *A. oryzae* transformants were reisolated twice on  
selective plates and enzyme activity of a stable transformant  
(MEA155) was analyzed by using tributylene as a substrate as  
25 described in Example 5.

## EXAMPLE 4

**Construction of a plasmid expressing the F135W/F139W variant of  
Candida antarctica lipase A**

A 246 bp BamHI/BssHII fragment was synthesized in vitro using 5 oligonucleotide primers 3116 and 4224 by a PCR reaction. The primer 4224 includes a BssHII restriction site and mutations in the 135 and 139 codons (TTC) to trp codons (TGG) which are marked with stars.

The oligonucleotide primer 3116 is shown in Example 2.

10 Oligonucleotide primer 4224 (F135W:566-487) (SEQ ID No. 11)  
5'-TTC TTG AGC GCG CGG ATG CCG TCG AGG ATA GCC ATG CCC TCT TCG  
TAG CCA GCG ATC\* C\*AG GCG GCT TTC\* C\*AG CCT TCG TG-3'

PCR reaction was performed by using the method shown in Example 2. The 310 bp fragment was isolated from a 2% agarose gel after 15 electrophoresis and digested with BamHI and BssHII restriction enzymes. The resulting 264 bp BamHI/BssHII fragment was likewise isolated from a 2% agarose gel. This fragment was then ligated with

20 pMT1229 BamHI/XbaI 0.3 kb  
pMT1229 BssHII/SphI 0.5 kb  
pMT1229 SphI/XbaI 5.0 kb

The ligated DNA was transformed into E. coli MT172. Transformants which contained inserts were selected and their DNA sequence was determined by use of Sequenase. One resulting 25 plasmid (pME1230) contained two mutations in the amino acid positions 135 and 139 (phe was mutated to trp).

pME1230 was cotransformed with pToC90 which included the amds gene from A. nidulans as a selective marker into A. oryzae A 1560 strain. A. oryzae transformants were reisolated twice on

, selective plates and enzyme activity of stable transformants were analyzed by using tributylene as a substrate as described in Example 5.

EXAMPLE 5

5 Purification of C. antarctica lipase A variants F139W and F135W/F139W and comparison of specific activity with their parent wild type C. antarctica lipase A

The lipase variants and the parent lipase produced as described in Examples 3, 4 and 1, respectively, were purified using the 10 following 4 step standard purification procedure.

Step 1: The fermentation broth containing the lipase and lipase variant, respectively, obtained by culturing the transformed A. oryzae cells described in Examples 1 and 3 above, was centrifuged, and the supernatant was adjusted to pH 7. Ionic strength 15 was adjusted to 2 mM. DEAE-Sephadex A-50 (Pharmacia) gel was swollen and equilibrated in 25 mM Tris acetate buffer pH 7. The fermentation supernatant was passed through DEAE-Sephadex A-50 on scintered glass funnel. The effluent containing lipase activity was collected and adjusted to 0.8 M ammonium acetate.

20 Step 2: An appropriate column was packed with TSK gel Butyl-Toyopearl 650 C and equilibrated with 0.8 M ammonium acetate. The effluent containing lipase activity was applied on the column. The bound material was eluted with water.

Step 3: The lipase-containing eluate was then applied on a 25 Highperformance Q-Sepharose column. Lipase activity was collected as effluent. The lipases purified by this method were concentrated to an Optical Density of 1 at 280 nm.

The purity of the lipases was checked by SDS-PAGE showing one band with an molecular weight of about 45 kD. The lipase

activity was determined by use of the method outlined above in the section "General methods".

The lipase activity of the parent wild type lipase was 300 LU/OD<sub>280</sub> as compared to 1200 LU/OD<sub>280</sub> for the lipase variant F139W. On the basis of OD<sub>280</sub> absorption without correction for the inserted tryptophan, the specific activity of the mutant was at least four times higher with the assay used. The lipase activity of the lipase variant F135W/F139W was 1400 LU/OD<sub>280</sub> (without correction for the two additional tryptophans).

#### 10 EXAMPLE 6

##### **Thermostability of *Candida antarctica* lipase A and the mutant F139W thereof**

The thermostability of the *C. antarctica* lipase A and the *C. antarctica* lipase A variant, was examined by Differential Scanning Calorimetry (DSC) at different pH values. Using this technique, the thermal denaturation temperature, T<sub>d</sub>, is determined by heating an enzyme solution at a constant programmed rate.

More specifically, the Differential Scanning Calorimeter, MC-20 2D, from MicroCal Inc. was used for the investigations. Enzyme solutions were prepared in 50 mM buffer solutions, cf. the tables below. The enzyme concentration ranged between 0.6 and 0.9 mg/ml, and a total volume of about 1.2 ml was used for each experiment. All samples were heated from 25°C to 90°C at a scan rate of 90°C/hr.

The results obtained from the analysis is shown in the table below:

*C. ant. lipase A (WT)*

pH	Buffer (50 mM)	Denaturation temperature <sup>1)</sup>
4.5	Acetate	96°C
5.5	Acetate	95°C
7	TRIS	93°C

*C. ant. lipase A mutant (F139W)*

pH	Buffer (50 mM)	Denaturation temperature <sup>1)</sup>
5	Acetate	84°C
7	TRIS	82°C

<sup>1)</sup> Temperature, at which approximately half the enzyme  
molecules present have been denatured thermally during  
heating

The above results show that the pH-optimum for the thermostability of *C. antarctica* lipase A and the F139W variant is unusually low and that both enzymes are very thermostable below pH 7. Within the investigated range the thermostability of both the Wild Type and the mutant F139W continues to increase as pH is lowered. This makes both lipases very well suited for hydrolysis/synthesis at unusually high temperatures at relatively low pH values.

## CLAIMS

1. A lipase variant of a parent lipase comprising a trypsin-like catalytic triad including an active serine located in a predominantly hydrophobic, elongated binding pocket of the 5 lipase molecule and, located in a critical position of a lipid contact zone of the lipase structure, an amino acid residue different from an aromatic amino acid residue, which amino acid residue interacts with a lipid substrate at or during hydrolysis, in which lipase variant said amino acid residue has been 10 replaced by an aromatic amino acid residue so as to confer to the variant an increased specific activity as compared to that of the parent lipase.
2. A lipase variant according to claim 1, wherein the aromatic amino acid residue to be inserted in the critical position is 15 selected from the group consisting of tryptophan, phenylalanine, tyrosine and histidine.
3. A lipase variant according to claim 1 or 2, in which said amino acid residue different from an aromatic amino acid residue is a phenylalanine residue.
- 20 4. A lipase variant according to any of claims 1-3, in which the amino acid residue located in the critical position of the lipase is different from tryptophan, and said amino acid residue has been replaced with a tryptophan residue.
5. A lipase variant according to any of the preceding claims, 25 wherein the parent lipase is selected from a microbial or a mammalian lipase.
6. A lipase variant according to claim 5, wherein the parent lipase is a yeast lipase.
7. A lipase variant according to claim 6, wherein the parent 30 lipase is derived from a strain of Candida antarctica.

8. A lipase variant according to claim 7, wherein the parent lipase is lipase A of C. antarctica.

9. A lipase variant according to claim 8, which has the amino acid sequence shown in SEQ ID No. 1, in which the phenylalanine 5 139 of the parent lipase has been replaced by a tryptophan residue, or in which the phenylalanine 135 and 139 of the parent lipase have been replaced by tryptophan residues.

10. A lipase variant according to claim 5, in which the parent lipase is a bacterial lipase.

10 11. A lipase variant according to claim 10, wherein the parent lipase is derived from a strain of Pseudomonas.

12. A lipase variant according to claim 11, which is derived from a strain of Ps. fragi.

13. A lipase variant according to claim 12, which has the amino acid sequence shown in SEQ ID No. 3 in which the phenylalanine 15 29 of the parent lipase has been replaced by a tryptophan residue.

14. A lipase variant according to claim 5, wherein the parent lipase is selected from a fungal lipase, a human lipase, a 20 murine lipase, a rat lipase or a canine lipase.

15. A C. antarctica lipase A essentially free from other substances from C. antarctica, which comprises the amino acid sequence shown in SEQ ID No. 2, or a variant of said lipase which

25 1) has lipase activity,

2) reacts with an antibody reactive with at least one epitope of C. antarctica lipase A having the amino acid sequence SEQ ID No. 2, and/or

, 3) is encoded by a nucleotide sequence which hybridizes with an oligonucleotide probe prepared on the basis of the full or partial nucleotide sequence shown in SEQ ID No. 1 encoding the C. antarctica lipase A.

5 16. A DNA sequence encoding C. antarctica lipase A having the amino acid sequence shown in SEQ ID No. 2 or a modification of said DNA sequence which encodes a variant of C. antarctica lipase A which

1) has lipase activity,

10 2) reacts with an antibody reactive with at least one epitope of the C. antarctica lipase A having the amino acid sequence SEQ ID No. 2, and/or

3) is encoded by a nucleotide sequence which hybridizes with an oligonucleotide probe prepared on the basis of the full or 15 partial nucleotide sequence shown in SEQ ID No. 1 encoding the C. antarctica lipase A.

17. A DNA construct comprising a DNA sequence encoding a lipase variant according to any of claims 1-14 or C. antarctica lipase A according to claim 15.

20 18. A recombinant expression vector which carries a DNA construct according to claim 17.

19. A cell which is transformed with a DNA construct according to claim 17 or a vector according to claim 18.

20. A cell according to claim 19 which is a fungal cell, e.g. 25 belonging to the genus Aspergillus, such as A. niger, A.-oryzae, or A. nidulans; a yeast cell, e.g. belonging to a strain of Saccharomyces, such as S. cerevisiae, or a methy-lotrophic yeast from the genera Hansenula, such as H. polymorpha, or Phichia, such as P. pastoris; or a bacterial cell,

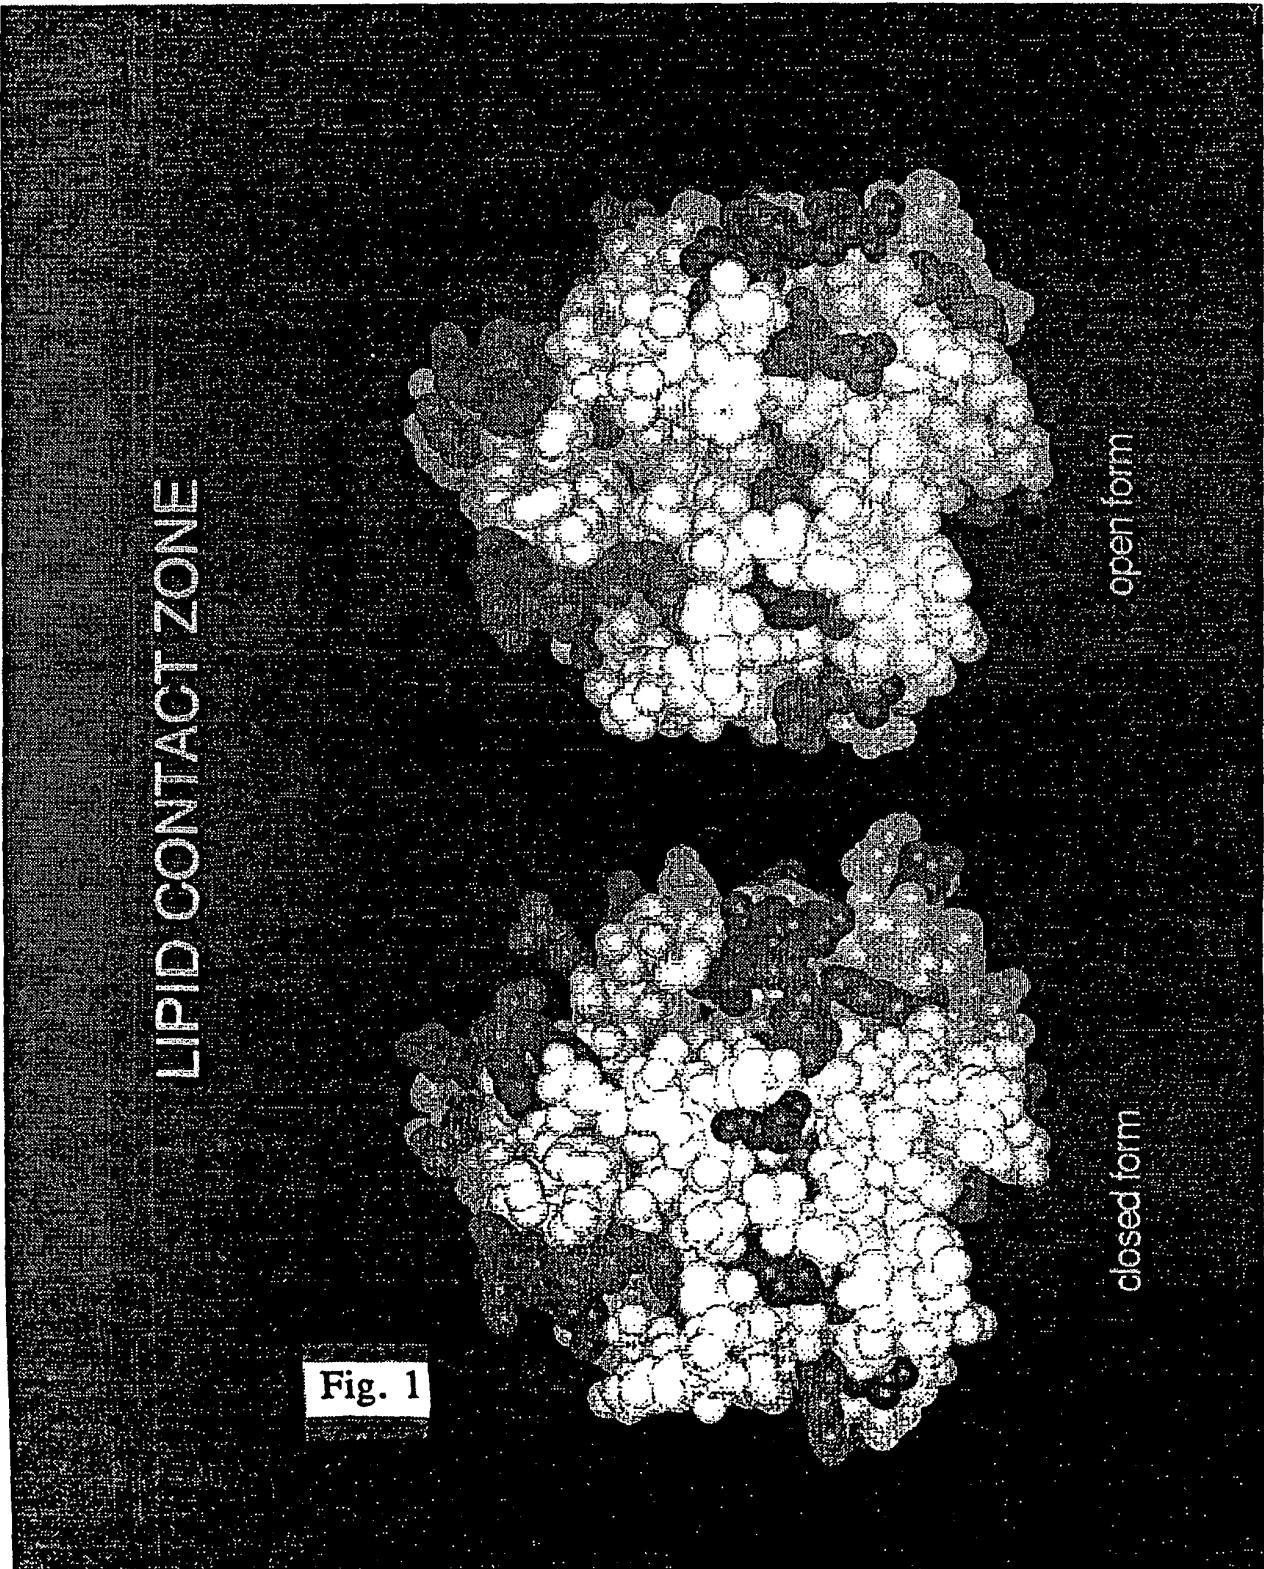

, e.g. belonging to a strain of Bacillus, such as B. subtilis, B. licheniformis or B. lentus, or to a strain of Escherichia, such as E. coli.

21. A method of producing a lipase variant according to any of claims 1-14, wherein a cell according to claim 19 or 20 is cultured under conditions conducive to the production of the lipase variant, and the lipase variant is subsequently recovered from the culture.

22. Use of a lipase variant according to any of claims 1-14 or 10 the C. antarctica lipase A or a variant thereof according to claim 15 in ester hydrolysis, ester synthesis or interesterification.

23. Use of a lipase variant according to any of claims 1-14 or 15 the C. antarctica lipase A or a variant thereof according to claim 15 for avoiding pitch trouble in a process for the production of mechanical pulp or a paper-making process using mechanical pulp.

I  
INTERNATIONAL SEARCH REPORT

International application No. PCT/DK 93/00225
--

## A. CLASSIFICATION OF SUBJECT MATTER

**IPC5: C12N 9/20, C12N 15/55 // (C 12 N 9/20, C 12 R 1:72)**  
 According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

**IPC5: C12N**

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

**SE,DK,FI,NO classes as above**

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

**WPI, CA, BIOSIS, MEDLINE**

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	WO, A1, 9205249 (NOVO NORDISK A/S), 2 April 1992 (02.04.92), see claim 1  --	1-14,17-23
A	EP, A1, 0407225 (UNILEVER PLC ET AL), 9 January 1991 (09.01.91), see the claims  --	1-14,17-23
A	EP, A1, 0305216 (NOVO INDUSTRI A/S), 1 March 1989 (01.03.89)  --	1-14,17-23
A	NATURE, Volume 351, June 1991, Joseph D. Schrag et al, "Ser-His-Glu triad forms the catalytic site of the lipase from Geotrichum candidum" page 761 - page 764  --	1-14,17-23

Further documents are listed in the continuation of Box C.

See patent family annex.

- \* Special categories of cited documents:
- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed
- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to person skilled in the art
- "&" document member of the same patent family

## C (Continuation). DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	Chemical Abstracts, Volume 118, No 1, 4 January 1993 (04.01.93), (Columbus, Ohio, USA), Sugihara, Akio et al, "Purification and characterization of a novel ther mostable lipase from Pseudomonas cepacia", page 301, THE ABSTRACT No 2772g, J. Biochem. 1992, 112 (5), 598-603  ---	15-20,22-23

**INTERNATIONAL SEARCH REPORT**

International application No.

PCT/DK 93/00225

**Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)**

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1.  Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
  
2.  Claims Nos.: because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
  
3.  Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

- I Claims 1-14, 21 part of claims 17-20 and part of claims 22-23 directed to a lipase variant
- II Claims 15-16, part of claims 17-20 and part of claims 22-23 directed to a Candida antarctica lipase A

1.  As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2.  As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3.  As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
  
4.  No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest**

- The additional search fees were accompanied by the applicant's protest.  
 No protest accompanied the payment of additional search fees.

**INTERNATIONAL SEARCH REPORT**
